

# AI for Cybersecurity: Three Applications for Network Security

Pierre-François Gimenez  
Inria researcher  
PIRAT research team

Summer School – AI-driven Cyber Security  
July 1st, 2025

# Who am I?

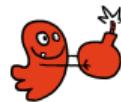

## Background

- 2018: PhD on machine learning at IRIT, Toulouse
- Since 2020: Researcher in a security team at Inria, Rennes
- I publish in both AI and security conferences

## AI ∩ Cybersecurity = ?

There are many applications of AI to cybersecurity!

- Side channel analysis
- Malware analysis
- Network intrusion detection
- Security data generation

# Who am I?

## Background

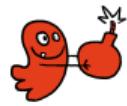

- 2018: PhD on machine learning at IRIT, Toulouse
- Since 2020: Researcher in a security team at Inria, Rennes
- I publish in both AI and security conferences

## AI ∩ Cybersecurity = ?

There are many applications of AI to cybersecurity!

- Side channel analysis
- Malware analysis
- **Network intrusion detection**
- **Security data generation**

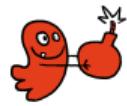

The following work were mostly done during Maxime Lanvin and Adrien Schoen PhDs

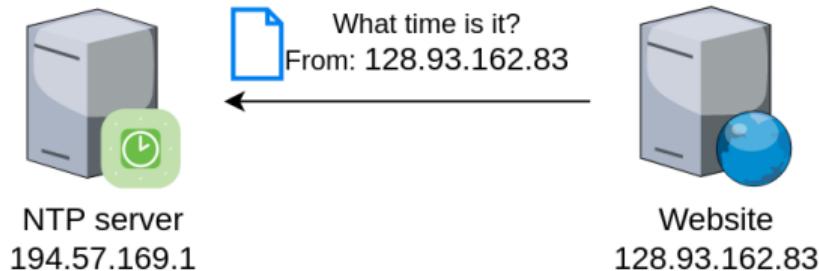

# Simple denial of service attack

Website  
128.93.162.83

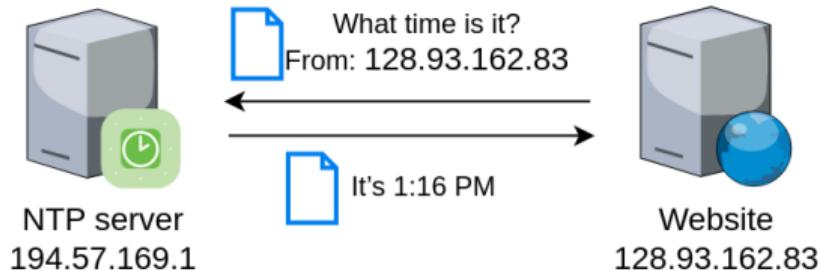

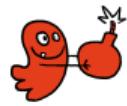

## Simple denial of service attack

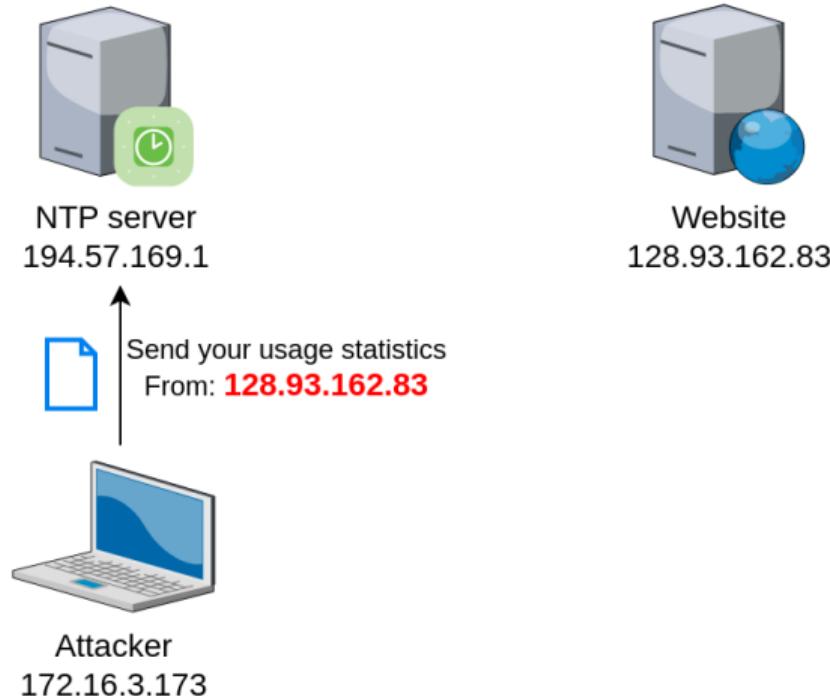

## Simple denial of service attack

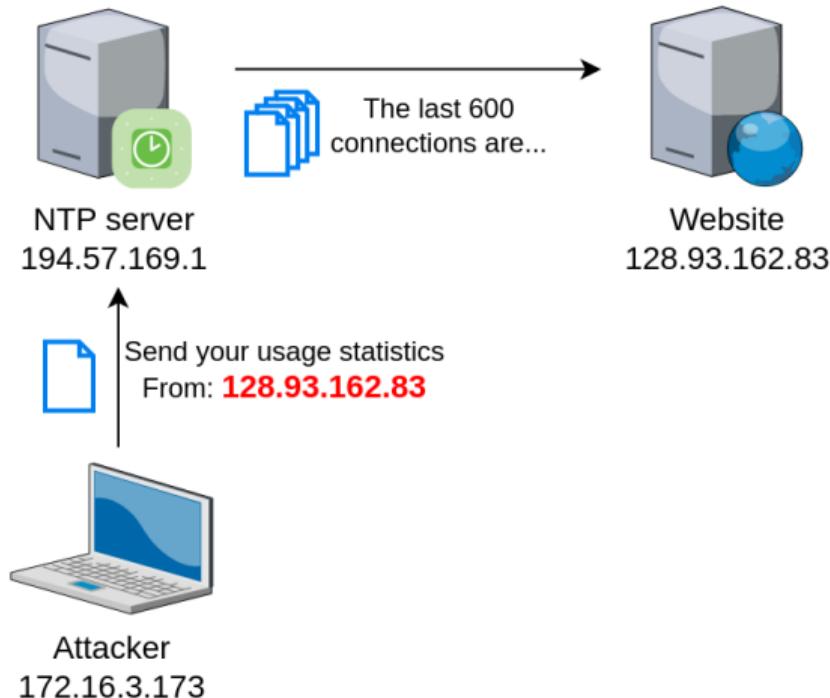

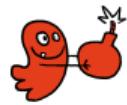

# Simple denial of service attack

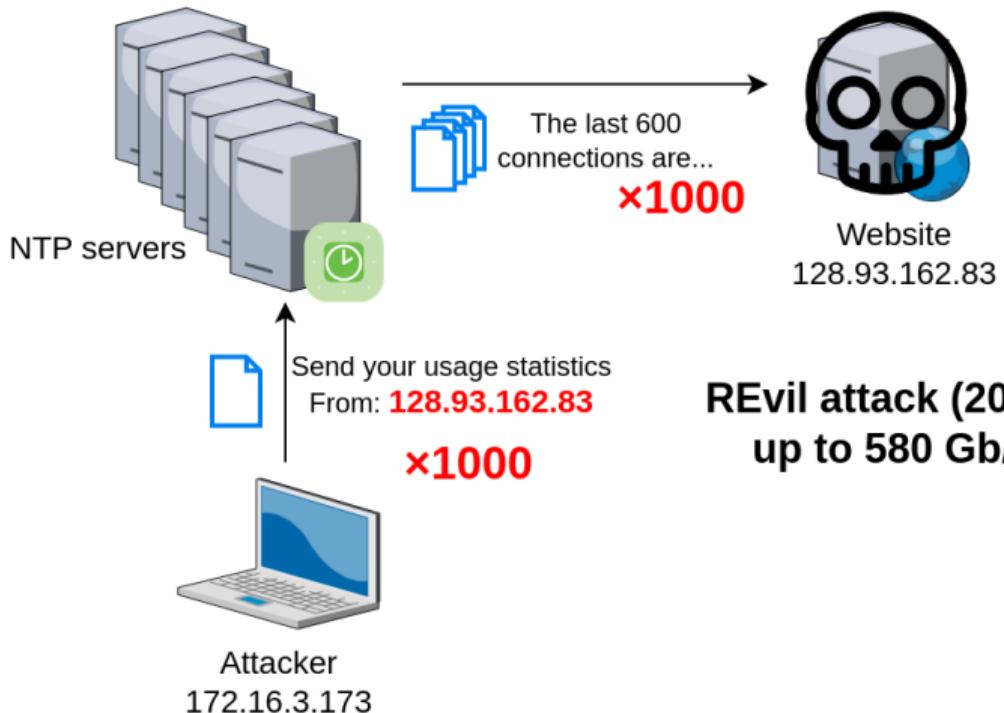

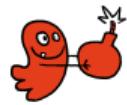

# Simple denial of service attack

## Simple denial of service attack

# Introduction

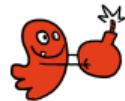

## Systems are under attack

- Many untargeted, opportunistic attacks like password bruteforce
- Some targeted attacks with a huge power (e.g., DDoS attacks)
- Some very sophisticated attacks months or years in the making (SolarWinds, Stuxnet...)

## Cloudflare defenses autonomously block a 7.3 Tbps DDoS attack

In May 2025, an attack delivered 37.4 terabytes in 45 seconds

# Information system security

## Information system security

- Prevent the attack, detect it, and react
- Detection with **IDS**: *Intrusion Detection System*

```
2024-05-06T23:24:16.806598+02:00
stellar-sheep sshd[16039]: Failed
password for pfg from 192.168.1.36
port 48650 ssh2
```

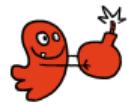

## Detection relies on observation

- **System**: OS and applications logs
- **Network**: network communications

```
"ts": 1591367999.305988,
"id.orig_h": "192.168.4.76",
"id.resp_h": "192.168.4.1",
"id.resp_p": 53, "proto": "udp",
"service": "dns", "duration":
0.066851, "orig_bytes":
62, "resp_bytes": 141,
"conn_state": "SF", "orig_pkts": 2,
"orig_ip_bytes": 118,
"resp_pkts": 2, "resp_ip_bytes": 197
```

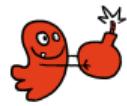

## Constraints

- Partial and heterogeneous observations
- Adversarial context: the attacker hides!

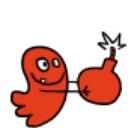

# Outline

- ① Introduction
- ② AI for network intrusion detection
- ③ Explainable AI for anomaly detection
- ④ AI for synthetic data generation
- ⑤ Conclusion

## AI for network intrusion detection

# Network data example

## Network data

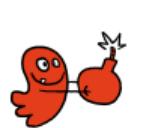

- Raw data consist of packets, regrouped in conversations
- Cybersecurity analysis typically rely on network flow records
- Network flows describe conversations statistically

No.	Time	Source	Destination	Protocol	Length	Info

## Two categories of detectors

### Signature-based detection

**Date:** 2024-04-25 10:24:52+02:00  
**Source IP:** 194.57.169.1  
**Destination IP:** 128.93.162.83

**Signature :** alert udp any any -> any 123 (content:"|00 02 2A|"; offset:1; depth:3; byte\_test:1,!&,128,0; byte\_test:1,&,4,0; byte\_test:1,&,2,0; byte\_test:1,&,1,0; threshold: type both, track by\_dst,count 2, seconds 60);

**Potential attack using NTP!**

### Signatures database

- + quick, clear
- regular updates, only documented attacks

### Anomaly detection

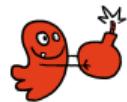

**Date:** 2024-04-25 10:24:52+02:00  
**Source IP:** 194.57.169.1  
**Destination IP:** 128.93.162.83

**Anomaly score: 7,6**

### Normal behavior model (generally with AI)

- + can detect undocumented attacks
- false positives, no alert description

## Two categories of detectors

### Signature-based detection

Date: 2024-04-25 10:24:52+02:00  
Source IP: 194.57.169.1  
Destination IP: 128.93.162.83

**Signature :** alert udp any any -> any 123 (content:"|00 02 2A|"; offset:1; depth:3; byte\_test:1,!&,128,0; byte\_test:1,&,4,0; byte\_test:1,&,2,0; byte\_test:1,&,1,0; threshold: type both, track by\_dst, count 2, seconds 60);

Potential attack using NTP!

### Signatures database

- + quick, clear
- regular updates, only documented attacks

### Anomaly detection

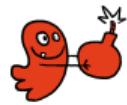

Date: 2024-04-25 10:24:52+02:00  
Source IP: 194.57.169.1  
Destination IP: 128.93.162.83

Anomaly score: 7,6

### Normal behavior model (generally with AI)

- + can detect undocumented attacks
- false positives, no alert description

# AI for network security

## The constraints of AI

- Typically, AI works on *vectors*
- These vectors must always have the same size
- In practice, it is not always the case

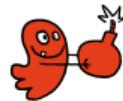

## The need of representation

Several techniques are used to transform data into a fixed vector

- Images are rescaled
- Words are split into subwords (tokens)

## In network security

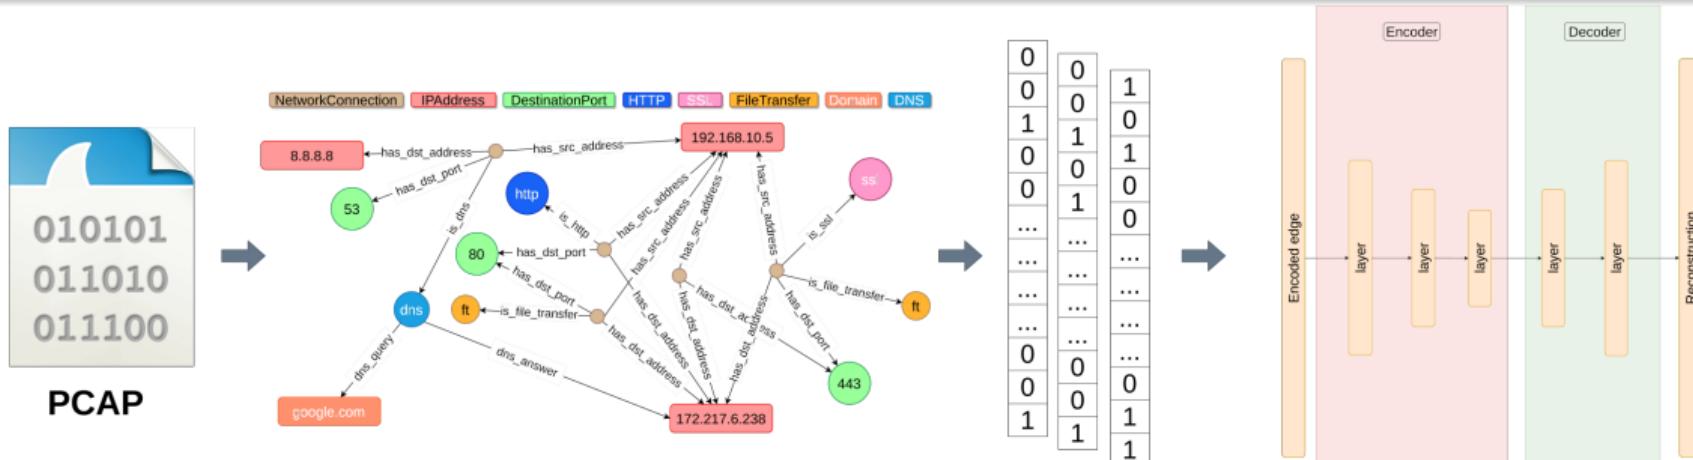

- Network flow are vectors
- There is no standard way to analyze *packets*

## Overview of our approach Sec2graph

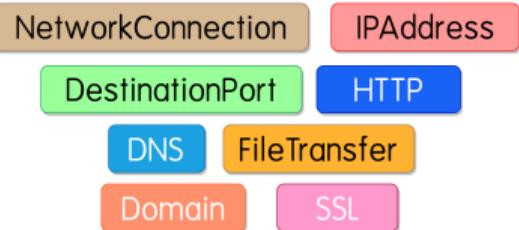

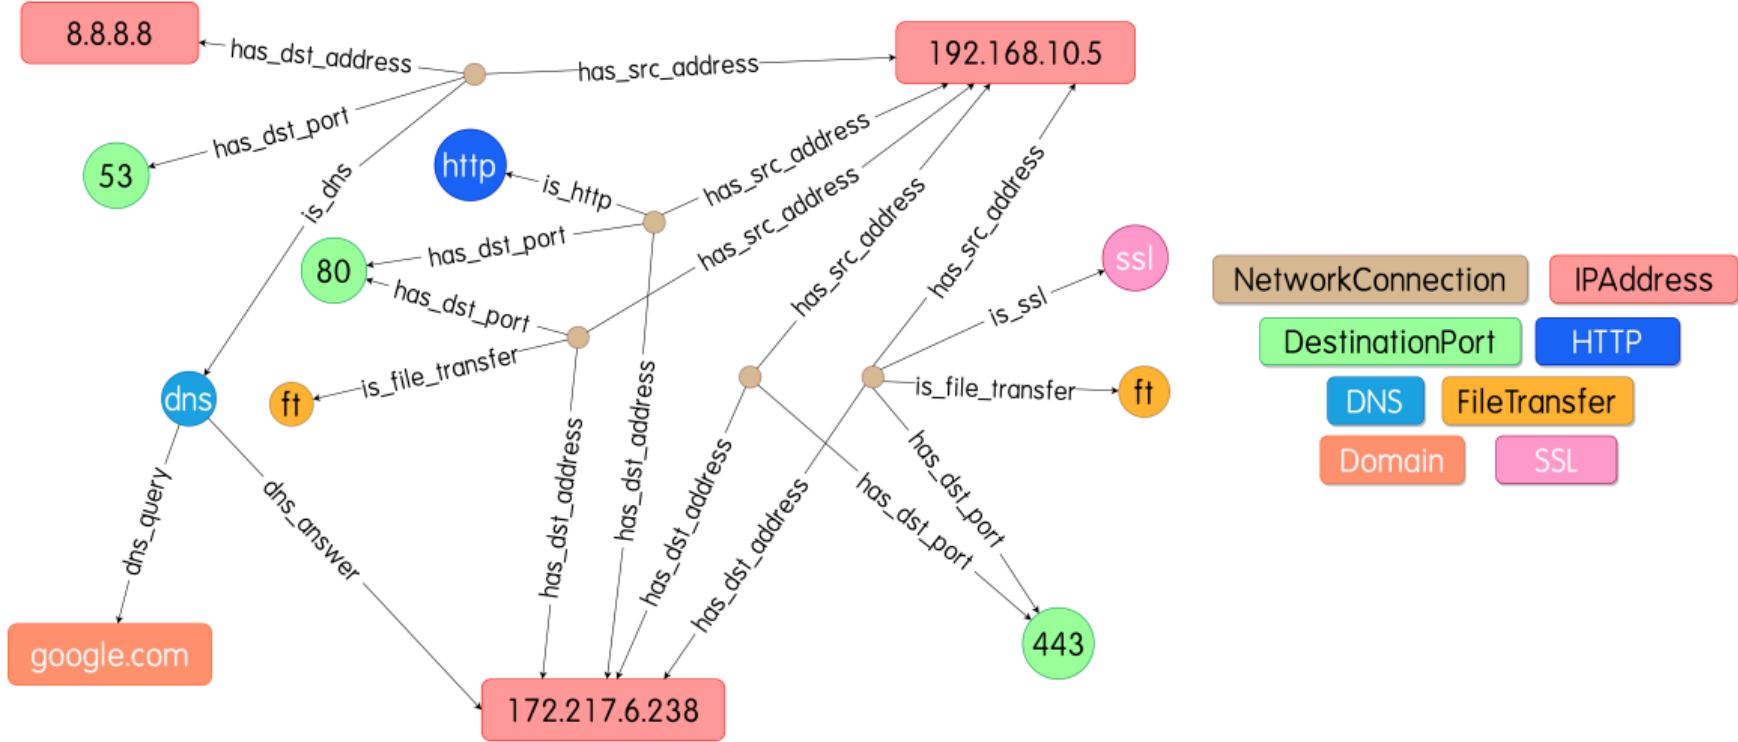

## Structure of our approach

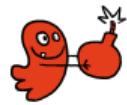

- Probes capture the network data
  - These data are merged into a graph structure
  - The graph is transformed into a format usable with a deep learning model
  - The model assigns an anomaly score to each data point

# Security objects graph example

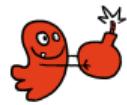

# Security objects graph

## Nodes

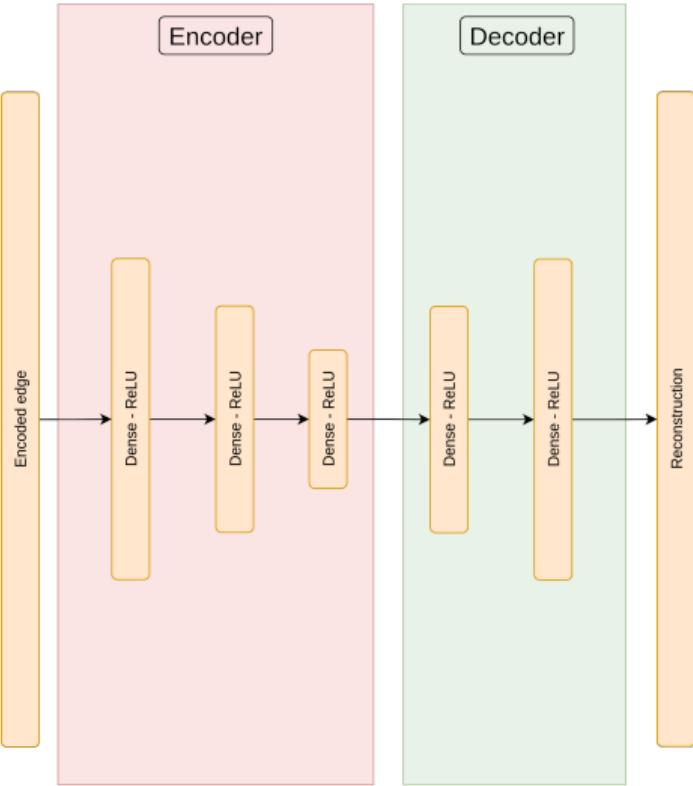

- Each node type corresponds to a "security object":
  - protocols: DNS, SSH, DCERPC, SNMP, FTP, DHCP, HTTP, SMTP
  - network data: port, MAC address, IP address, network connection, URI, domain
  - and others
- Nodes contain a set of attributes related to these objects

## Edges

- Edges are typed and oriented
- They do not contain attributes
- An edge between two nodes means that these two nodes are found within the same event

# Anomaly detection: Autoencoder (AE)

## Autoencoder

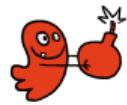

An autoencoder is a deep learning architecture with a bow-tie shape

## Learning

Minimisation of the reconstruction error between the input vector and its reconstructed version

## Detection

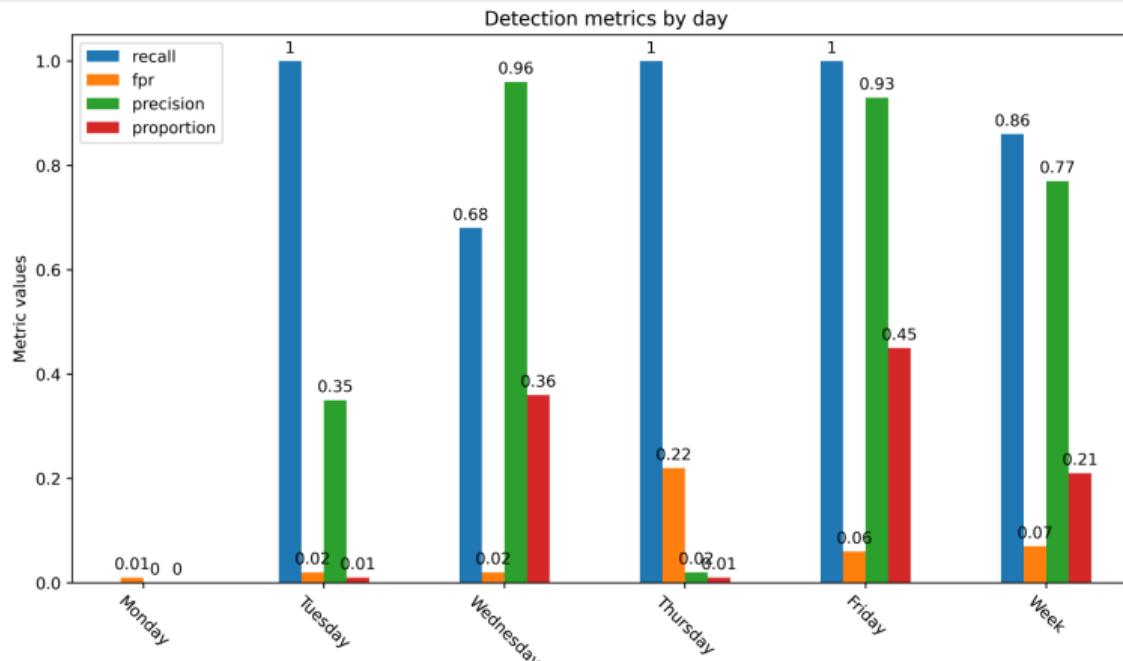

Raise an alert when the reconstruction error is above a threshold

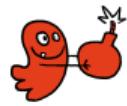

# Performances on CIC-IDS2017

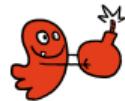

## Performances

Recall is mostly good but we have a very high false positive (22%!) on Thursday

## Explainable AI for anomaly detection

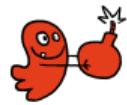

## How to explain the predictions?

### The issue

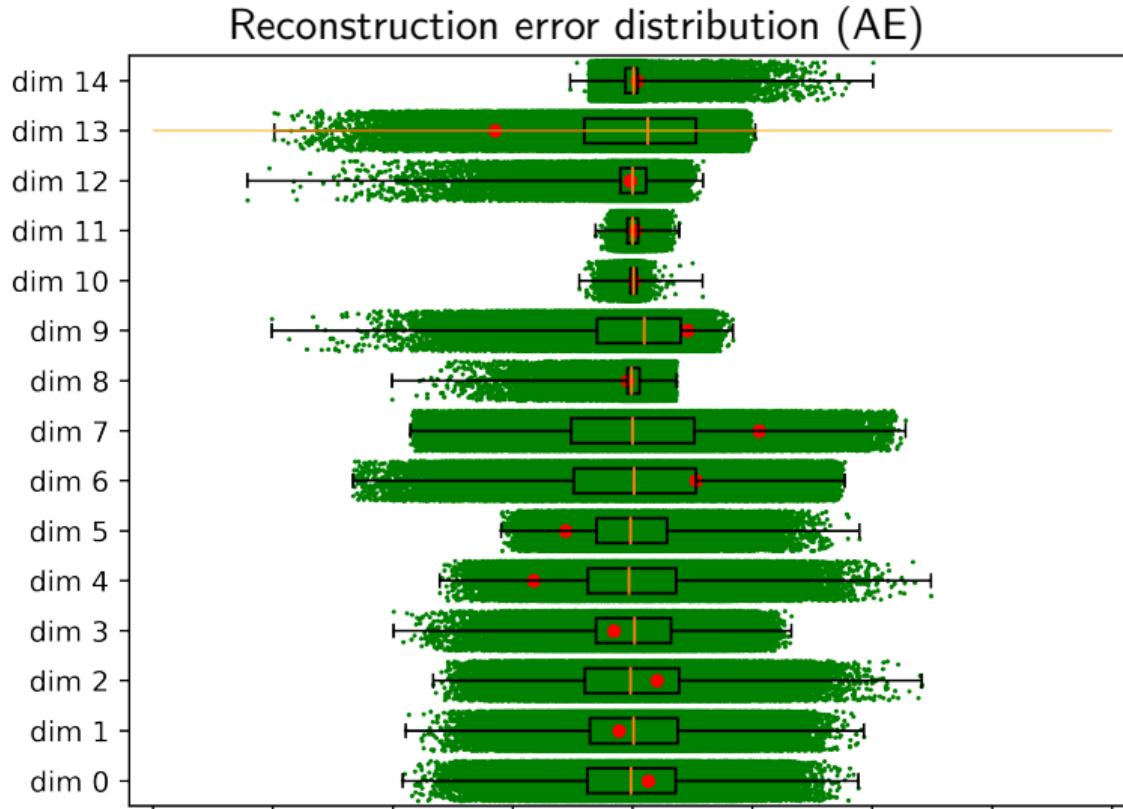

- Explanations could help us understand the false positives
- There exists a lot of explanation techniques... (LIME, salient maps, counterfactual explanation...)
- ...but little work on explanations for unsupervised learning!

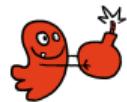

### First, naive approach

- We can compute the contribution of each feature to the global reconstruction error
- However, we found out this idea does not produce satisfactory explanations:
  - Some features are always difficult to reconstruct because of their high variance
  - Some features are always very faithfully reconstructed, and even a small reconstruction error may reveal an anomaly

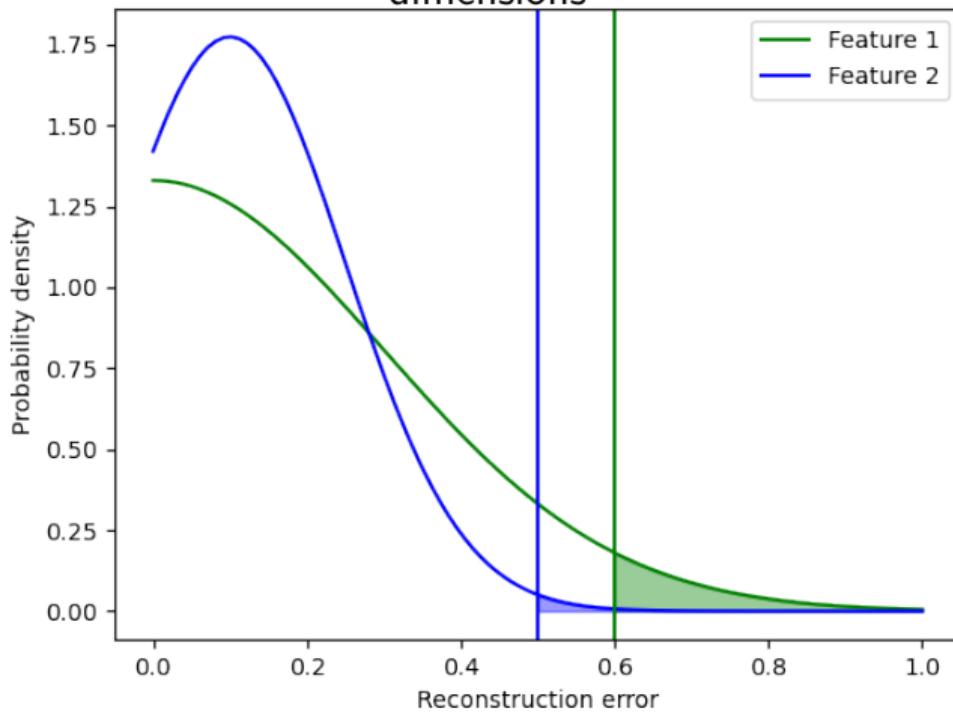

## What it looks like

## Limitations

Comparison of the reconstruction errors of two dimensions

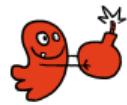

### Key Idea

The highest reconstruction error is not always an indication of the most abnormal dimension.

### Our approach

This area is called the p-value:

$$p_i = \frac{\#\{r_i \geq e_i\}}{\#\{r_i\}}$$

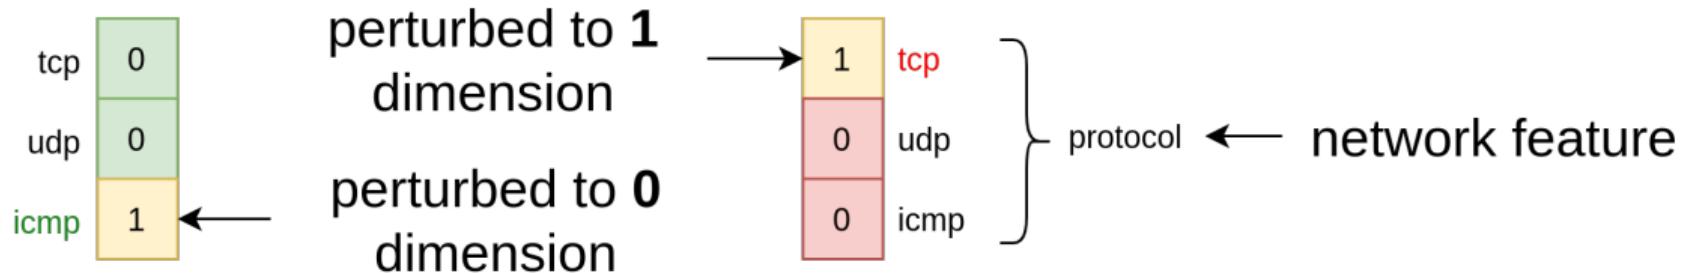

# Experimental protocol

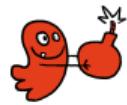

## Protocol

- Inject noise in a known network characteristic of vectors
- Assess ability of XAI methods to find the noisy network characteristic

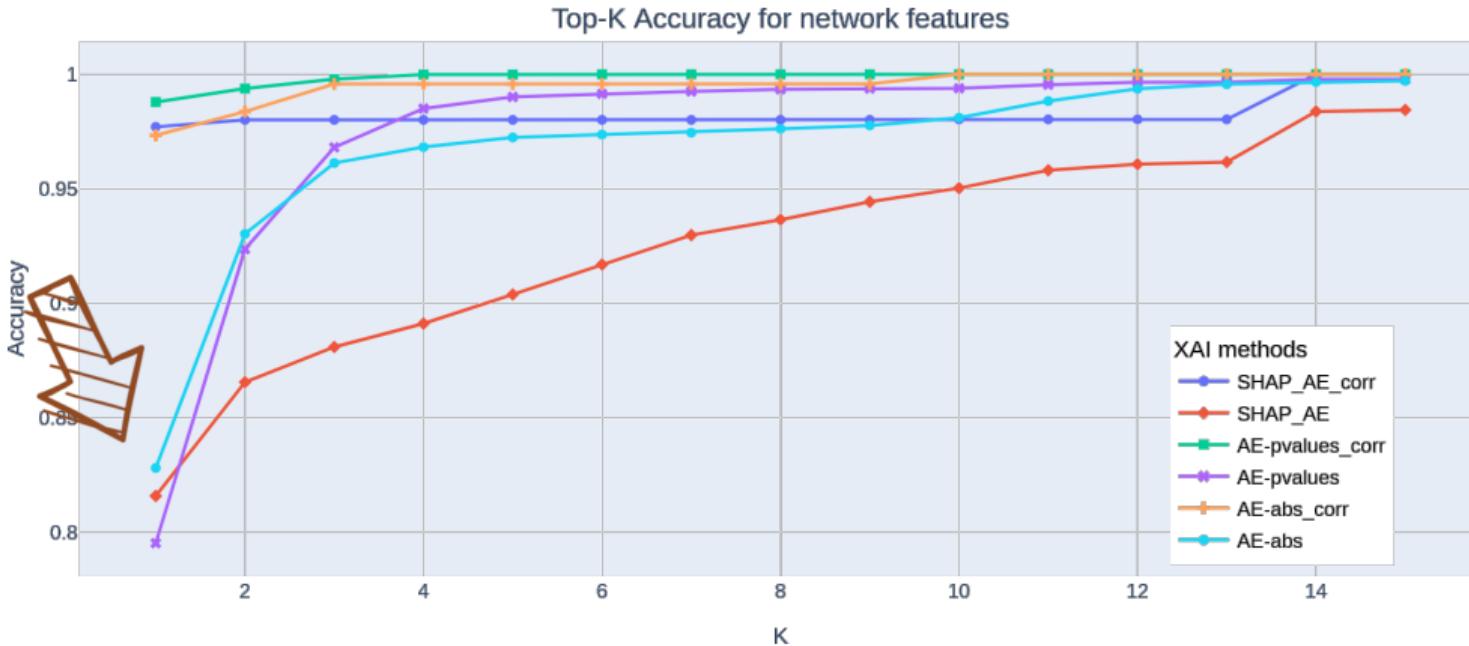

Experiment with AE-abs (intuitive method), SHAP\_AE (state of the art), AE-pvalues (our method)

## Example of noise insertion in the protocol characteristic

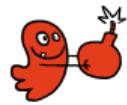

## Benchmark results

### Top-K accuracy

Proportion of samples for which the right explanation is among the Top-K explanations. But sometimes several explanations are correct...

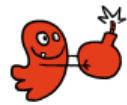

## Several correct explanations

$$1 + 1 = 0$$

Where is the error?

We can all agree there is an error. But where do you think it is?

- \* 0 should be 2
- \* + should be -
- \* 1 should be -1
- \* = should be >
- \* "(mod 2)" is missing
- \* "is false" is missing

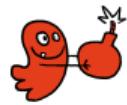

## Several correct explanations

$$1 + 1 = 0$$

Where is the error?

We can all agree there is an error. But where do you think it is?

- 0 should be 2
- + should be -
- 1 should be -1
- = should be >
- "(mod 2)" is missing
- "is false" is missing

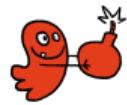

## Several correct explanations

$$1 + 1 = 0$$

Where is the error?

- = should be >
- "(mod 2)" is missing
- "is false" is missing

## Benchmark results

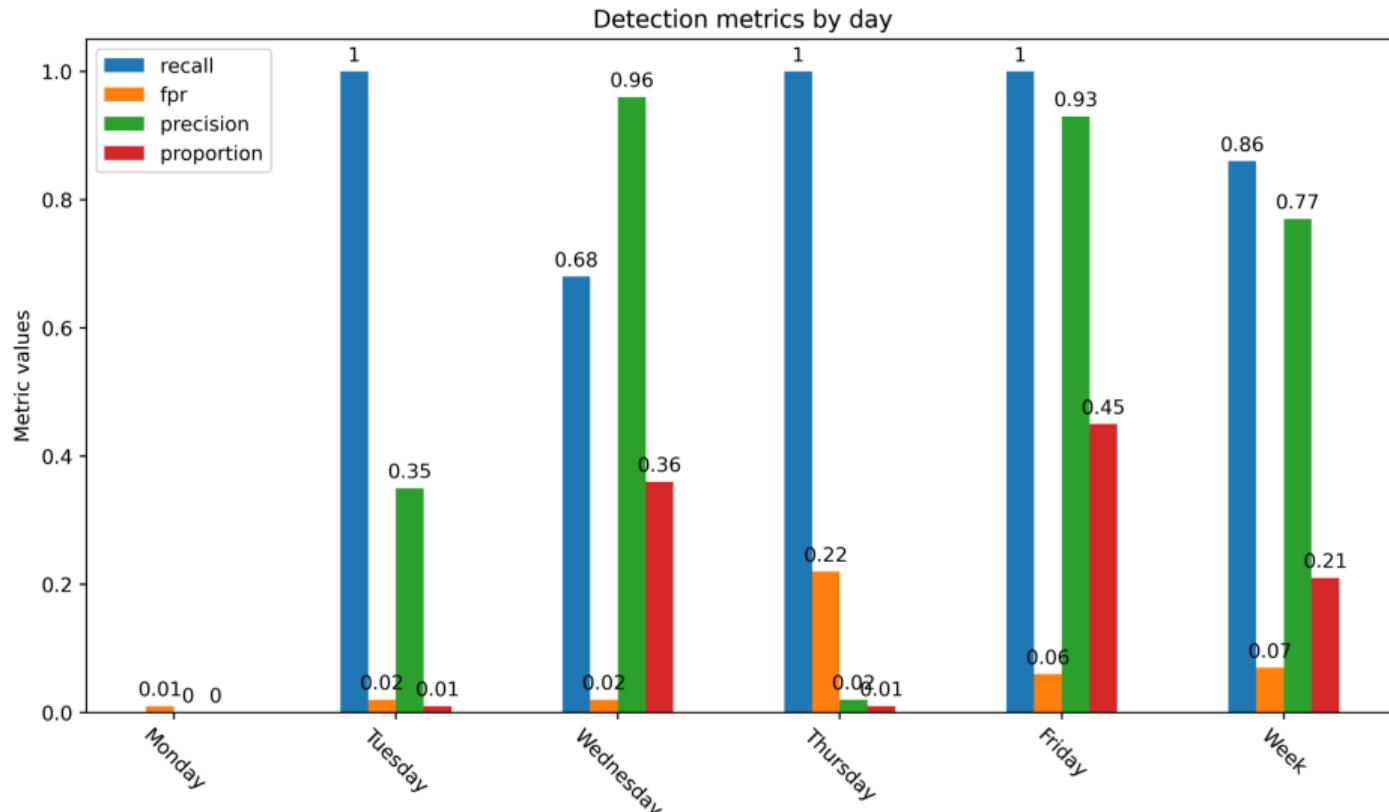

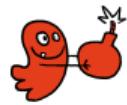

A more realistic evaluation

Evaluation modification: accepting correlated features as correct explanations

## Remember that?...

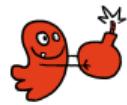

## What is the issue with CIC-IDS2017?

Not only one...

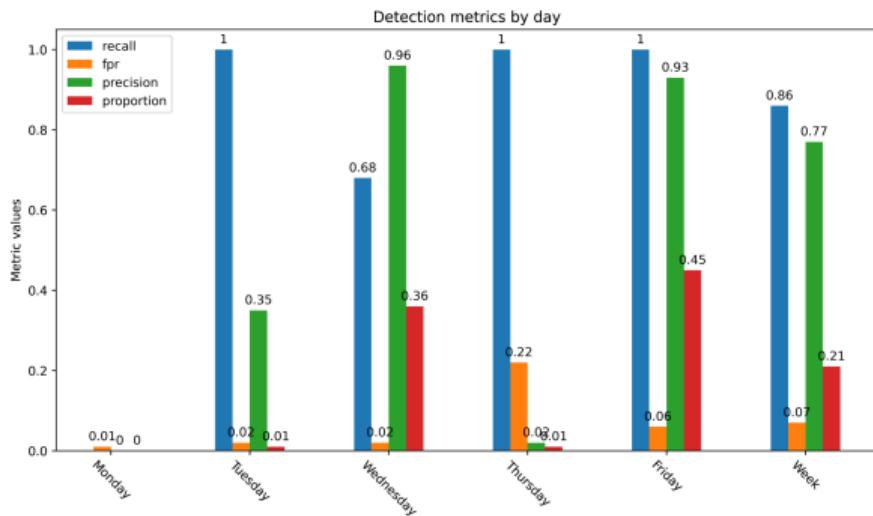

- Labeling issue: CIC-IDS2017 has a scan attack on Thursday that is not correctly labeled. About 70,000 flows of scan are labeled as "benign"!
- Duplication issue: probably due to a badly configured probe, on average 500,000 packets are duplicated per day. It caused the CSV files to contain bad data
- Shortcut learning possible: the tools use their default user agent
- And a few minor issues

Corrected CIC-IDS2017 files: <https://gitlab.inria.fr/mlanvin/crisis2022>

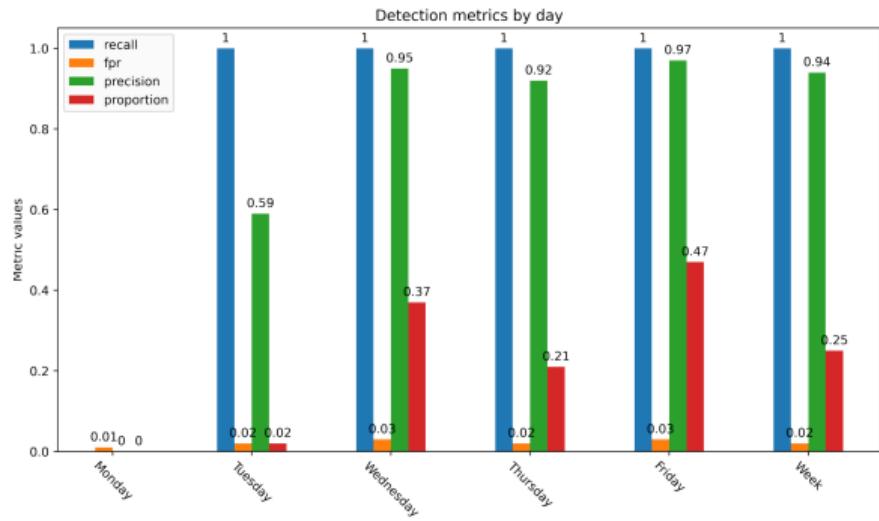

These results make us confident in the usefulness of our explanation method

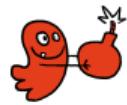

# Updated results on CIC-IDS2017

Before CIC-IDS2017 correction

After CIC-IDS2017 correction

## Flawed datasets

### Public dataset

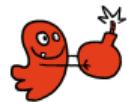

- Most IDS research relies on public dataset
- It allows for reproducible results and comparison between methods
- A few datasets are popular: NSL-KDD, CIC-IDS-2017/2018, and a few others

### Criticisms

We are not the only ones finding issues in datasets

- NSL-KDD is still used but obsolete
- 4 articles have been published on issues on CIC-IDS-2017 alone
- Other datasets are also criticized

Common issues: unrealistic testbed, duration too low, badly configured tool and probe...

## Alternatives

### Real data

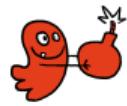

- Difficult to obtain/share due to confidentiality and privacy reasons
- Typically not labeled

### Testbeds

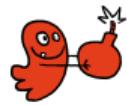

- Difficult to create: it must include fake users with online activity with a wide range of behaviors
- Slow: we need one month to generate one month of data

### Data generation with AI

- Could be much faster than testbed
- Is AI mature enough? How to explain the generation process and to evaluate the data?

## AI for synthetic data generation

# GenAI: GANs

## Generative Adversarial Networks

Two neural networks compete: one to generate fake data, the second one to find whether some data is fake or genuine

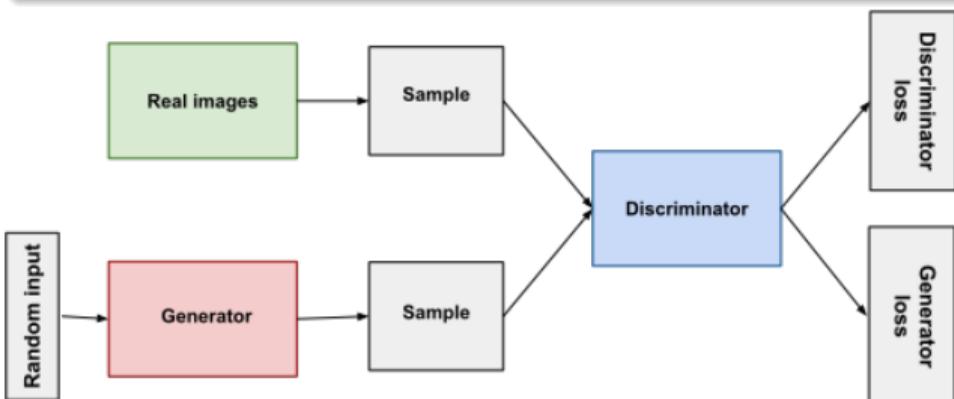

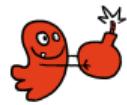

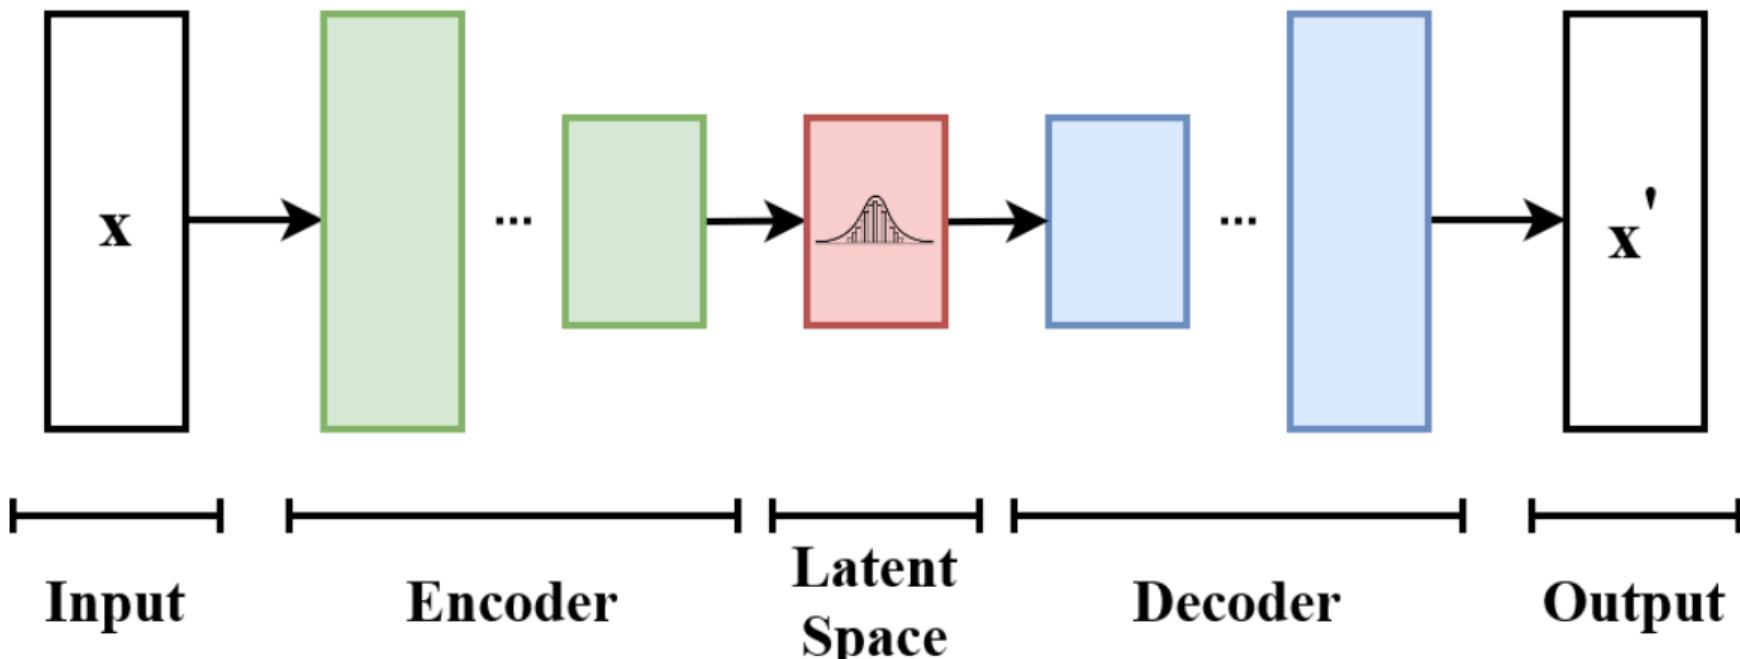

Image generated with StyleGAN (2019)

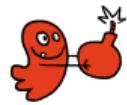

## GenAI: VAEs

### Variational AutoEncoders

An autoencoder used to generate data by decoding random vectors in the latent space

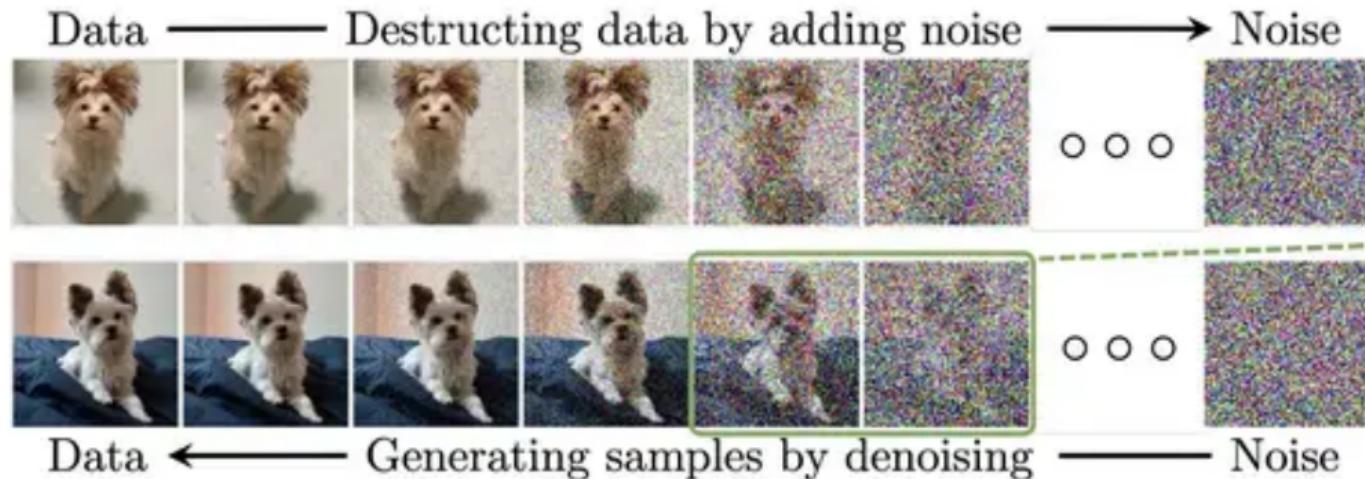

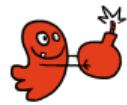

## GenAI: diffusion models

### Diffusion models

A model trained to "denoise" data. Applied several times in a row to create images from noise.

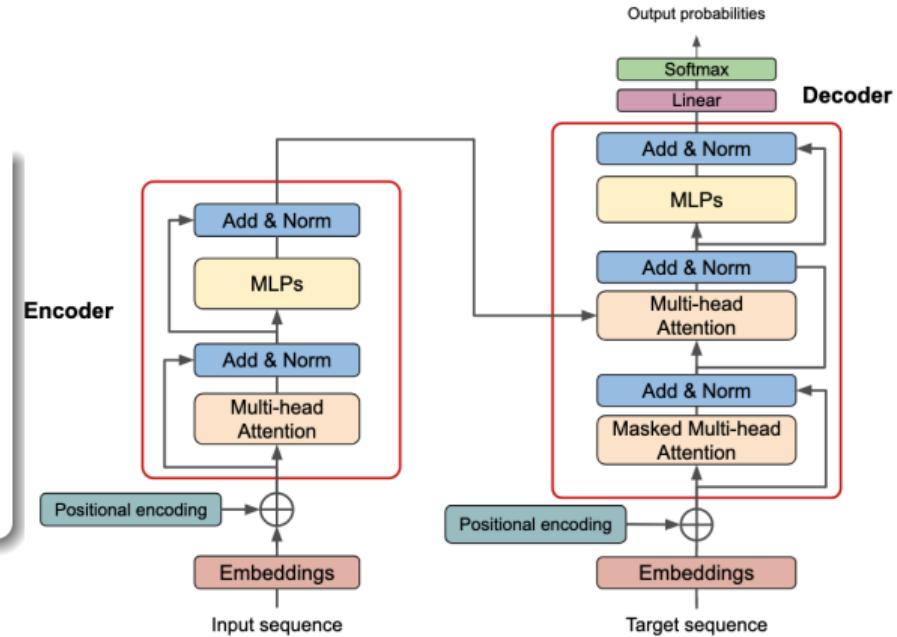

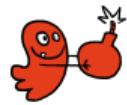

# GenAI: LLMs

## Transformers

- A model that predicts the next token based on the previous ones. The generation focuses on the relevant tokens in the context window
- It is the base of LLMs: ChatGPT, Gemini, Mistral, Llama, etc.

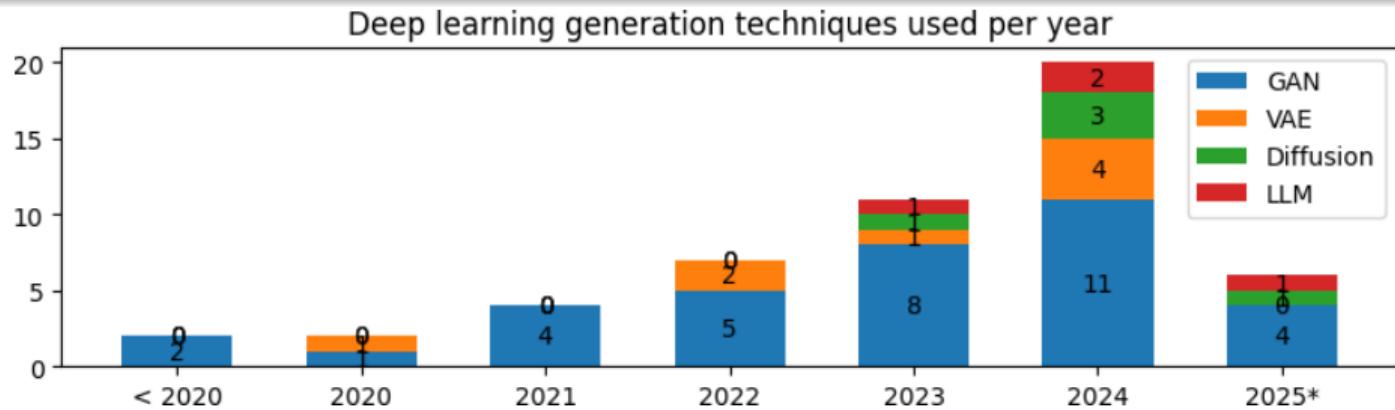

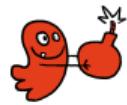

# GenAI for network generation

And in network generation?

- A quick growth of works on synthetic network traffic generation
- All previous techniques are used to generate synthetic network traffic
- However, the quality of the generated data is still low
- Lack of explainability makes progress slower

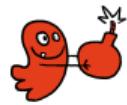

# GenAI for network generation

A big limitation: dependencies within the data

- Intra-flow dependency
  - the port depends on the destination IP
  - the number of packets depends on the application protocol
- Inter-flow dependency:
  - DNS query then HTTP(S)
  - IMAP request then HTTP(S)

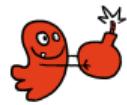

## Our work

We propose FlowChronicle as an explainable generation method not based on deep learning

## FlowChronicle: a novel approach

- Pattern language
  - Captures intra-flow and inter-flow dependencies
  - Summarizes data with non-redundant patterns
- Data generation
  - Produces realistic traffic respecting protocols
  - Preserves temporal dependencies
- Explainability
  - Patterns are interpretable and auditable

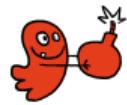

## What is a pattern?

Frequently occurring substructure in data

## Pattern Mining

- Define the set of possible patterns, named the "pattern language"
- Find a small set of patterns that best describes the data
- More precisely, we use the patterns to compress the data: higher the compression, better the patterns

## Pattern description

### Pattern language

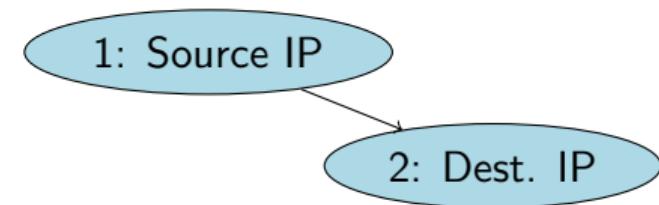

Each pattern has two parts: a partially defined flow, and a Bayesian network

- **Fixed** values are defined in the partial flow
- the distribution of **Free** variables is defined in the Bayesian network
- **Reused** variables are always equal to some **Free** variable

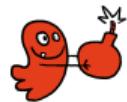

#### Partial flows

Source IP	Dest. IP	Dest. Port
$\beta_A$	8.8.8.8	53
A	$\beta$	80

#### Bayesian Network

In reality there are more columns!

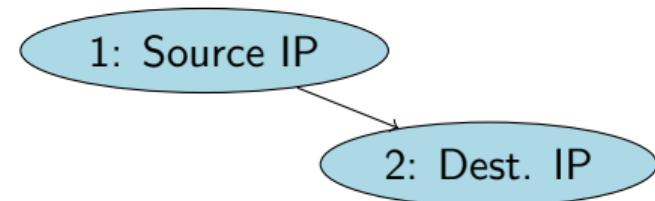

## Pattern description

### Partial flows

Source IP	Dest. IP	Dest. Port
$\beta_A$	8.8.8.8	53
A	$\beta$	80

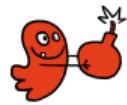

### Bayesian Network

### Example

- Here, there are two flows
- The first flow is contacting 8.8.8.8 on port 53 (DNS). The source IP is random
- The second flow has the same source IP as the first flow, and is contacting a destination IP that is random and depends on the first source IP, on port 80 (HTTP)

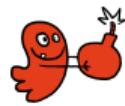

Our goal is to learn ("mine") such patterns

# Pattern mining algorithm

## Pattern Search:

- ① Initialize Model with an empty pattern
- ② Generate Pattern Candidates from existing patterns  $p \in M$ .
  - By extending with an attribute
  - By merging existing patterns
- ③ Test candidates for addition:
  - Cover the datasets with the patterns
  - Add patterns when it reduces MDL score:  $L(D | M) + L(M)$

## Dataset cover

## Model – Pattern and Bayesian Network:

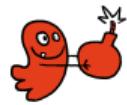

$\epsilon$  : [  $\beta \ \beta \ \beta$  ] 1:Src IP 1:Dst IP 1:Port

$$p : \begin{bmatrix} \beta_A & \beta & 993 \end{bmatrix} \quad \begin{array}{c} 1:\text{Src IP} \\ 2:\text{Dst IP} \end{array} \quad \begin{array}{c} 1:\text{Dst IP} \end{array}$$

<b>q</b>	[	$\beta_A$	8.8.8.8	52	]	1:Src IP
	[	A	$\beta_B$	443	]	2:Dst IP
	[	B	$\beta$	3306	]	3:Dst IP

### Data and Pattern Windows:

Time	Src IP	Dst IP	Port
12	134.96.235.78	142.251.36.5	993
56	134.96.235.129	8.8.8.8	52
89	134.96.235.78	212.21.165.114	80
113	134.96.235.129	198.95.26.96	443
145	198.95.26.96	198.95.28.30	3306
156	134.96.235.78	134.96.234.5	21
178	134.96.235.36	185.15.59.224	993
206	134.96.235.36	128.93.162.83	80

## Loss function

Length of data given the model:

$$L(D | M) = \sum_{p \in M} (L_N(|W_p|) + L(W_p))$$

where:

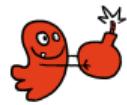

$$L(W_p) = \sum_{i=1}^{|W_p|} \left( L(t_1 \text{ of } w_i) + \sum_{k=2}^{|p|} L(t_k \text{ of } w_i | t_{i-1}) \right) - \log(Pr(w_i | BN_p, \{w_j | j < i\}))$$

Length of Model:

$$L(M) = L_N(|M|) + \sum_{p \in M} L(p)$$

Length of one pattern:

$$L(p) = L_N(|p|) + \left( \sum_{j=1}^{|p|} L(X[j] | p) \right) + L(BN_p)$$

# Data quality evaluation

## Hard to evaluate

- No standard metrics
- Evaluation often partial

## Proposition

A set of evaluating metrics:

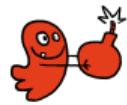

**Realism** : could the data actually exist?

**Diversity** : do we generate the diversity of behavior from the training set?

**Novelty** : can the generator create data absent from the training set?

**Compliance** : do the generated data comply with the technical specifications?

We do not consider privacy yet

## Experimental protocol

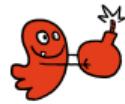

### Training data

We use the CIDDS 001 dataset: train on one week of traffic and generate one week of traffic

### Baselines

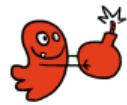

We compare FlowChronicle with:

- Bayesian networks
- VAE
- GAN
- Transformers
- "Reference": actual data from the same dataset to simulate the best generative method

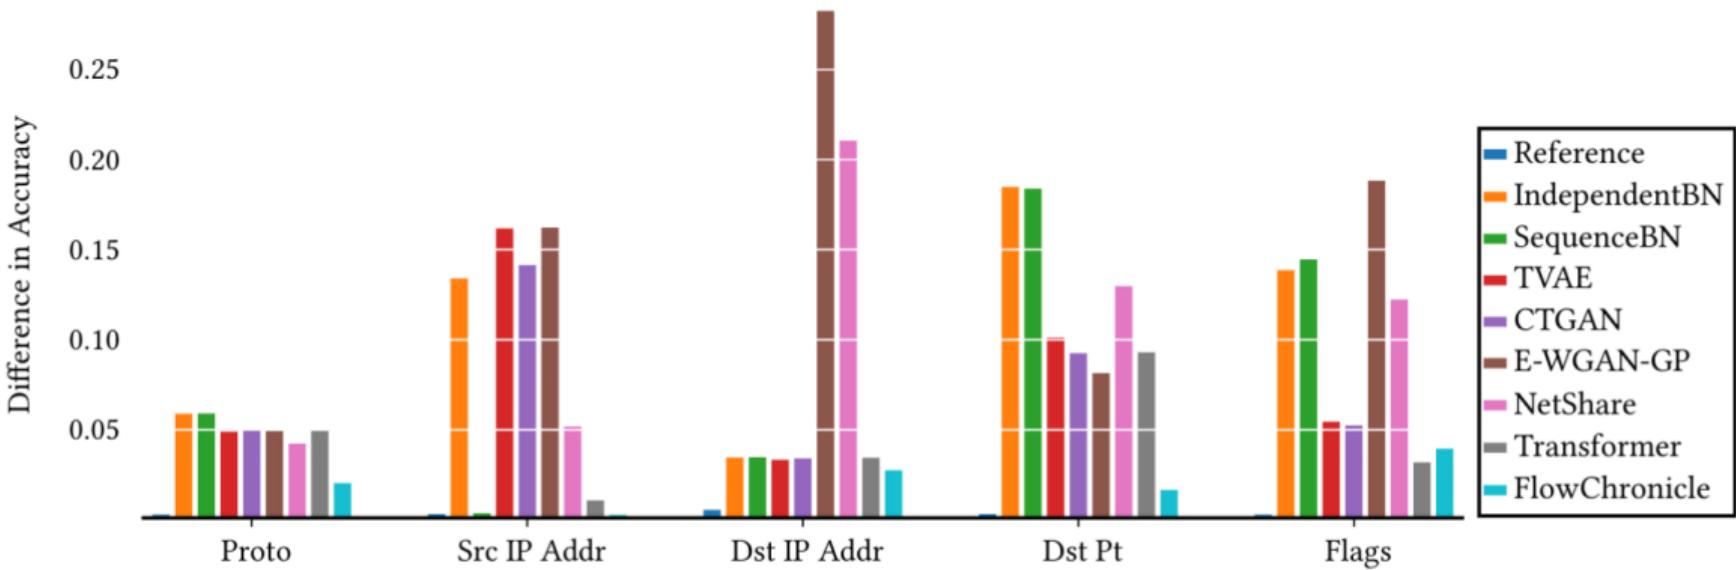

## FlowChronicle: generation quality

## FlowChronicle: temporal generation quality

Overall, FlowChronicle outperforms other GenAI techniques and is explainable

## Conclusion

## Conclusion

AI + Cybersecurity = ❤

- There are many applications of AI to cybersecurity
- I presented three of them:
  - Network intrusion detection
  - Explainable AI for anomaly detection
  - Synthetic network traffic generation

### Current limits of AI

- AI is not a silver bullet for cybersecurity (yet)
- AI-based IDS still raise too many false positives
- Lack of explainability is a big drawback
- Generation performances are not that great

But AI's progress is fast and some of these limits could soon disappear
